

Regular grammar (Model regular grammars)

Difficulty Level : Expert • Last Updated : 26 Apr, 2022

Prerequisites: [Chomsky hierarchy](#)

Type-3 grammar/regular grammar:

Regular grammar generates regular language. They have a single non-terminal on the left-hand side and a right-hand side consisting of a single terminal or single terminal followed by a non-terminal.

The productions must be in the form:

$$A \rightarrow xB$$
$$A \rightarrow x$$
$$A \rightarrow Bx$$

where $A, B \in \text{Variable}(V)$ and $x \in T^*$ i.e. string of terminals.

Types of regular grammar:

- Left Linear grammar (LLG)
- Right linear grammar (RLG)

1. Left linear grammar (LLG):

In LLG, the productions are in the form if all the productions are of the form

$$A \rightarrow Bx$$

$$A \rightarrow x$$

where $A, B \in V$ and $x \in T^*$

2. Right linear grammar(RLG):

In RLG, the productions are in the form if all the productions are of the form

$$A \rightarrow xB$$

$$A \rightarrow x$$

where $A, B \in V$ and $x \in T^*$

The language generated by type-3 grammar is a regular language, for which a FA can be designed. The FA can also be converted into type-3 grammar

Example: FA for accepting strings that start with b

$$\Sigma = \{a, b\}$$

Initial state(q_0) = A

Final state(F) = B

The above grammar is RLG, which can be written directly through FA.

This grammar derives strings that are stated with B

The above RLG can derive strings that start with b and after that any input symbol (i.e. $\Sigma = \{a, b\}$ can be accepted).

The regular language corresponding to RLG is

$L = \{b, ba, bb, baa, bab, bba, bbb, \dots\}$

If we reverse the above production of the above RLG, then we get

$A \rightarrow Bb$

$B \rightarrow \epsilon / Ba / Bb$

It derives the language that contains all the strings which end with b.

i.e. $L' = \{b, bb, ab, aab, bab, abb, bbb, \dots\}$

So we can conclude that if we have FA that represents language L and if we convert it, into RLG, which again represents language L, but after reversing RLG we get LLG which represents language L' (i.e. reverse of L).

For converting the RLG into LLG for language L, the following procedure needs to be followed:

This represents the same procedure as above for converting RLG to LLG

Here L is a language for FA and L^R is a reversal of the language L .

Example:

The above FA represents language L (i.e. set of all strings over input symbols a and b which start with b).

We are converting it into LLG.

Step1: The reversal of FA is

The reversal of FA represents all strings starting with b .

Step 2: The corresponding RLG for this reversed FA is

$$B \rightarrow aB/bB/bA$$

$$A \rightarrow \epsilon$$

Step 3: The reversing the above RLG we get

$$B \rightarrow Ba/Bb/Ab$$

$$A \rightarrow \epsilon$$

So this is LLG for language L (which represents all strings that start with b).

$$L = \{b, ba, bb, baa, bab, bba, bbb, \dots\}$$

Conversion of RLG to FA:

Example: The RLL grammar for Language(L), represents a set of all strings which end with 0.

$$A \rightarrow 0A/1B/0B$$

$$B \rightarrow \epsilon$$

So the FA for corresponding to RLG can be found out as

Start with variable A and use its production.

- For production $A \rightarrow 0A$, this means after getting input symbol 0, the transition will remain in the same state.
- For production, $A \rightarrow 1B$, this means after getting input symbol 1, the state transition will take place from State A to B.
- For production $A \rightarrow 0B$, this means after getting input symbol 0, the state transition will take place from State A to B.
- For production $B \rightarrow \epsilon$, this means there is no need for state transition. This means it would be the final state in the corresponding FA as RHS is terminal.

So the final NFA for the corresponding RLG is

Set of all strings that end with 0

Conversion of LLG to FA:

Explanation: First convert the LLG which represents the Language (L) to RLG, which represents, the reversal of language L (i.e. L^R) then design FA corresponding to it (i.e. FA for Language L^R). Then reverse the FA. Then the final FA is FA for language L).

Conversion of LLG to RLG: For example, the above grammar is taken which represents language L (i.e. set of all strings that start with b)

The LLG for this grammar is

$B \rightarrow Ba/Bb/Ab$

$A \rightarrow \epsilon$

Step 1: Convert the LLG into FA (i.e. the conversion procedure is the same as above)

Step 3: Write RLG corresponding to reversed FA.

$$A \rightarrow bB$$

$$B \rightarrow aB/bB/\epsilon$$

LLG \longleftrightarrow RLG

They can be easily converted to other

All have the same power and can be converted to other
